

3. Pokémon TCG Database Modeling Exercise

Diagram

Justification

In order to model the database of the game, 10 tables are proposed. Each one has a clear role, but they all work together so the system can store and manage everything needed for the game to run smoothly. The **Player** table represents each user, keeping their basic information and progress. The **Card** table defines every card in the game and what it does, acting as a reference for all the other card related features. The **Deck** table represents the decks created by players, allowing them to organize their strategies.

The **Collection** table stores the cards that each player owns, essentially working as their personal inventory. To handle this more precisely, the **Collection_Card** table links players to specific cards and keeps track of how many copies they have. In a similar way, the **Deck_Card** table shows which cards are included in each deck and in what quantity, making it possible to follow the rules for building a valid deck.

The **Match** table represents a game between two players, storing who is playing and the outcome. The **Match_State** table goes a step further by saving the progress of each match, such as turns and board state, so the game can continue smoothly and even be resumed later if needed. The **Store_Item** table includes the items available for purchase in the game, while the **Purchase** table records what each player buys.
